#### Introduction

Since the use of High-throughput sequencing (HTS) was first introduced to analyze immunoglobulin (B-cell receptor, antibody) and T-cell receptor repertoires (Freeman et al, 2009; Robins et al, 2009; Weinstein et al, 2009), the increasing number of studies making use of this technique has produced enormous amounts of data and there exists a pressing need to develop and adopt common standards, protocols, and policies for generating and sharing data sets. The Adaptive Immune Receptor Repertoire (AIRR) Community formed in 2015 to address this challenge (Breden et al, 2017) and has stablished the set of minimal metadata elements (MiAIRR) required for describing published AIRR datasets (Rubelt et al, 2017) as well as file formats to represent this data in a machine-readable form. The airr R package provides to read, write an validate data following the AIRR Data Representation standards. This vignette provides a set of simple use examples.

#### AIRR Data Representation Standards

The AIRR Community's recommendations for a minimal set of metadata that should be used to describe an AIRR-seq data set when published or deposited in a AIRR-compliant public repository are described in Rubelt et al, 2017. The primary aim of this effort is to make published AIRR datasets FAIR (findable, accessible, interoperable, reusable); with sufficient detail such that a person skilled in the art of AIRR sequencing and data analysis will be able to reproduce the experiment and data analyses that were performed.

Following this principles, V(D)J reference alignment annotations are saved in standard tab-delimited format files (TSV) with associated metadata provided in accompanying YAML formatted files. The column names and field names in these files have been defined by the AIRR Community using a controlled vocabulary of standardized terms and types to refer to each piece of information.

#### Reading AIRR formatted files

The airr package contains the function read\_rearrangement to read and validate files containing Rearrangement records in the AIRR Data Representation standards, where a Rearrangement record describes the collection of optimal annotations on a single sequence that has undergone V(D)J

reference alignment. The usage is straightforward, as the file format is a typical tabulated file. The argument that needs attention is base, with possible values "0" and "1". base denotes the starting index for positional fields in the input file. Positional fields are those that contain alignment coordinates and names ending in "\_start" and "\_end". If the input file is using 0-based coordinates with half-open intervals (python style), as defined by the standard, then positional fields will be converted to 1-based closed intervals (R style) using the default setting of base="0". If base="1" is specified, then positional fields will not be modified.

```
library(airr)
```

```
example_data <- system.file("extdata", "rearrangement-example.tsv.gz", package="airr")</pre>
basename(example_data)
## [1] "rearrangement-example.tsv.gz"
airr_rearrangement <- read_rearrangement(example_data, base="0")</pre>
class(airr_rearrangement)
## [1] "tbl_df"
                    "tbl"
                                  "data.frame"
head(airr rearrangement)
## # A tibble: 6 x 33
##

#### Writing AIRR formatted files

The airr package contains the function write\_rearrangement to write Rearrangement records to the AIRR TSV format.

```
out_file <- file.path(tempdir(), "airr_out.tsv")
write_rearrangement(airr_rearrangement, out_file, base="0")</pre>
```
